Chlorine dioxide is effective in the remediation of bacterial and sulfide contamination commonly found in oil field production, injection and disposal fluids. The required dosages will vary with process conditions. Sodium chloride may be applied either continuously or intermittently through a chlorine dioxide generating system to achieve the chlorine dioxide residual concentration between 0.1 and 5.0 ppm. Intermediate treatments should be repeated as necessary to maintain control.

Bacterial Control in Oil Wells And Petroleum Systems

Chlorine dioxide is effective in the remediation of bacterial and sulfide contamination commonly found in oil field production, injection and disposal fluids. The required dosages will vary with process conditions. Sodium chloride may be applied either continuously or intermittently through a chlorine dioxide generating system to achieve the chlorine dioxide residual concentration between 0.1 and 5.0 ppm.
